COMPUTER & CYBER FORENSICS

Weekly task list

A fictional office export contains a document inventory and activity log. Determine what the export supports about a report revision, without claiming access to an original disk.

The investigation question

What does the export support about changes to the report, and where does attribution remain uncertain?

Your four weekly tasks

Week 1 | Evidence intake and integrity

Inventory every file in the supplied training ZIP; assign evidence IDs CC-01 onward and record size, SHA-256, source and collection time. Create separate originals and working folders. Hash before analysis and explain why copying an export is not a forensic disk acquisition.

Output: evidence_register.csv, sha256_manifest.csv, preservation_notes.pdf

Week 2 | File metadata examination

Examine file_inventory.csv without editing the preserved copy. List each document version, supplied metadata and missing original-file properties. Compare report v1 and v2 metadata to the activity log. Identify conflicting or ambiguous records without assuming which source is correct.

Output: metadata_comparison.csv and examination_notes.pdf

Week 3 | Correlated activity timeline

Normalize all supplied timestamps to UTC and retain their original forms in a second column. Create a minimum eight-event timeline linking log records to inventory entries; flag events with no independent corroboration.

Output: timeline.csv, two_hypotheses.pdf and annotated references

Week 4 | Case report and peer handover

Produce a 4-6 page report answering whether the supplied export supports a revision, who or what is named in logs, and what cannot be concluded. Include scope, methods, tool versions, hash checks, evidence citations, alternative explanations and limitations.

Output: final_report.pdf, timeline.csv, hash_manifest.csv and handover.pdf

Read pages 2-5 for the full checklists. Submission rules follow on page 6; requirements and installation are on pages 7-8. Worked methods and three reading downloads are on page 9. The complete roadmap is the final page.

WEEK 1 | TASK INSTRUCTIONS

Evidence intake and integrity

Objective

Create a trustworthy baseline before interpreting any record.

Do this in order

1. Inventory every file in the supplied training ZIP; assign evidence IDs CC-01 onward and record size, SHA-256, source and collection time.

2. Create separate originals and working folders. Hash before analysis and explain why copying an export is not a forensic disk acquisition.

3. Write a chain-of-custody table with custodian, action, timestamp, purpose and integrity result.

4. Create a case note naming file_inventory.csv and activity.csv. For each, record evidence ID, original filename, byte size, SHA-256 and where the PFSA ZIP was downloaded. Keep the supplied manifest with the ZIP.

5. Distinguish a filename, a version label and an actual file hash. Do not hash a CSV row and describe it as the hash of a missing report.

6. Recheck one result independently: return to the source, repeat the calculation or lookup, and record whether it agrees. Keep a short correction log instead of silently revising previous findings.

Required hand-in

evidence_register.csv, sha256_manifest.csv, preservation_notes.pdf

Name the upload PFSA_<student-id>_computer-cyber_W1.pdf or .zip. A ZIP may contain the report plus CSV, SQL, images or other permitted supporting work. Do not rename a non-PDF file to .pdf. Keep the one portal upload below 10 MB.

Portal description and acceptance check

Write at least 200 genuine words in the description box: what you examined, how you processed it, exact evidence references, results, uncertainty and what you learned. Before submitting, open the uploaded work locally, confirm all filenames resolve, and compare original-file hashes with your intake record.

WEEK 2 | TASK INSTRUCTIONS

File metadata examination

Objective

Turn source records into a documented examination worksheet.

Do this in order

1. Examine file_inventory.csv without editing the preserved copy. List each document version, supplied metadata and missing original-file properties.

2. Compare report v1 and v2 metadata to the activity log. Identify conflicting or ambiguous records without assuming which source is correct.

3. Build an observation table with evidence ID, exact row reference, observation, interpretation and confidence.

4. Keep all original columns from file_inventory.csv and activity.csv. Add new analysis columns rather than replacing source identifiers or timestamps. Preserve the query, formula or filter used.

5. Compare event timestamps with the inventory timestamp and note that these are different fields with different meanings.

6. Recheck one result independently: return to the source, repeat the calculation or lookup, and record whether it agrees. Keep a short correction log instead of silently revising previous findings.

Required hand-in

metadata_comparison.csv and examination_notes.pdf

Name the upload PFSA_<student-id>_computer-cyber_W2.pdf or .zip. A ZIP may contain the report plus CSV, SQL, images or other permitted supporting work. Do not rename a non-PDF file to .pdf. Keep the one portal upload below 10 MB.

Portal description and acceptance check

Write at least 200 genuine words in the description box: what you examined, how you processed it, exact evidence references, results, uncertainty and what you learned. Before submitting, open the uploaded work locally, confirm all filenames resolve, and compare original-file hashes with your intake record.

WEEK 3 | TASK INSTRUCTIONS

Correlated activity timeline

Objective

Correlate events without hiding uncertainty or alternative explanations.

Do this in order

1. Normalize all supplied timestamps to UTC and retain their original forms in a second column.

2. Create a minimum eight-event timeline linking log records to inventory entries; flag events with no independent corroboration.

3. Test two explanations for the report revision: expected editing and an unverified account action. List what evidence would distinguish them.

4. Give every derived timeline event an exact source file and row or event ID. Record raw time, UTC time, conversion rule, evidence meaning and uncertainty in separate fields.

5. Check all file_record references against record_id. Explain whether a repeated version label represents independent source evidence.

6. Recheck one result independently: return to the source, repeat the calculation or lookup, and record whether it agrees. Keep a short correction log instead of silently revising previous findings.

Required hand-in

timeline.csv, two_hypotheses.pdf and annotated references

Name the upload PFSA_<student-id>_computer-cyber_W3.pdf or .zip. A ZIP may contain the report plus CSV, SQL, images or other permitted supporting work. Do not rename a non-PDF file to .pdf. Keep the one portal upload below 10 MB.

Portal description and acceptance check

Write at least 200 genuine words in the description box: what you examined, how you processed it, exact evidence references, results, uncertainty and what you learned. Before submitting, open the uploaded work locally, confirm all filenames resolve, and compare original-file hashes with your intake record.

WEEK 4 | TASK INSTRUCTIONS

Case report and peer handover

Objective

Deliver a clear, reproducible report that answers the case question.

Do this in order

1. Produce a 4-6 page report answering whether the supplied export supports a revision, who or what is named in logs, and what cannot be concluded.

2. Include scope, methods, tool versions, hash checks, evidence citations, alternative explanations and limitations.

3. Add a one-page handover checklist another student can reproduce from the training ZIP.

4. Write an executive summary first, then scope, evidence register, tool versions, reproducible methods, findings, alternatives, limitations and conclusion. Put detailed tables and queries in appendices.

5. Keep account labels such as service-B separate from a named human. A log label alone does not prove who operated the computer.

6. Recheck one result independently: return to the source, repeat the calculation or lookup, and record whether it agrees. Keep a short correction log instead of silently revising previous findings.

Required hand-in

final_report.pdf, timeline.csv, hash_manifest.csv and handover.pdf

Name the upload PFSA_<student-id>_computer-cyber_W4.pdf or .zip. A ZIP may contain the report plus CSV, SQL, images or other permitted supporting work. Do not rename a non-PDF file to .pdf. Keep the one portal upload below 10 MB.

Portal description and acceptance check

Write at least 200 genuine words in the description box: what you examined, how you processed it, exact evidence references, results, uncertainty and what you learned. Before submitting, open the uploaded work locally, confirm all filenames resolve, and compare original-file hashes with your intake record.

AFTER THE WEEKLY TASK LIST

Submission & assessment

What to submit each week

Submit one main project file and a separate portal narrative of at least 200 words. Use a PDF for a readable report; use a ZIP when the report needs supporting CSV, SQL, JSON, screenshots or source code. The portal supports multiple work formats, but it is not a substitute for organising your evidence.

Item	Required content
Main report	Student ID, domain, week, case question, scope, method, findings and limitations.
Appendices	Source references, derived tables, saved formulas/queries, tool versions and relevant screenshots.
Integrity record	Original file hashes and verification result; explain whether any working file changed.
Portal narrative	At least 200 words written in your own words; a report attachment does not replace this field.

A useful 200-word narrative structure

Use approximately 40-60 words for scope and inputs, 60-90 for your actual method, 60-90 for supported findings, and 40-60 for uncertainty and learning. These are writing prompts, not text to copy. Mention at least two precise record references and one limit of the evidence. Do not repeat a sentence or paste filler just to reach the counter.

Marking rubric | 100 marks per week

Criterion	Marks	What a reviewer looks for
Integrity and scope	20	Correct baseline, preserved originals and a defined question.
Method	25	Reproducible steps, versions, calculations and saved filters.
Analysis	25	Supported reasoning and alternatives, with appropriate uncertainty.
Evidence references	20	Exact file and row/event references for each significant finding.
Communication	10	Clear report, organised package and meaningful portal description.

Calendar deadlines and any resubmission instructions are published in the portal by staff. Four submissions unlock the next document stage; payment confirmation, project assessment and document publication remain staff-controlled. Ask Support about an incorrect upload or locked record.

LAPTOP, SOFTWARE & FILES

Requirements before you begin

Laptop and workspace

Use a laptop or desktop with a supported Windows, macOS or Linux installation, a keyboard and permission to install the required applications. For these small training exports, 4 GB RAM is a practical minimum; 8 GB is recommended. Reserve at least 2 GB free for tools and working files, with additional space for downloaded books. A phone can read PDFs and check portal status, but a laptop is strongly recommended for evidence tables, file packaging and reproducible work.

Required software for this domain

LibreOffice Calc and Writer; VS Code or another plain-text editor; Python 3 is optional for repeatable CSV checks. No disk imaging software is required for these exported tables.

Common tools and their purpose

Tool	Use in the assignment
LibreOffice Calc	Import CSVs, retain text identifiers, calculate summaries and save derived tables.
LibreOffice Writer	Write the case report and export it as a readable PDF.
Plain-text editor / VS Code	Inspect JSON, JSONL, SQL and notes without altering formatting in a word processor.
Native SHA-256 utility	Create and compare an integrity baseline for each source file.
Browser and PDF reader	Read the guide, open references and submit work through the student portal.

Training files and folder structure

Download computer-cyber-training-data.zip from the matching domain card. Its central source files are file_inventory.csv and activity.csv. Save the original ZIP, extract it once, and create four folders: originals, working, analysis and submission. Put the original extracted files in originals, analysis copies in working, derived outputs in analysis, and only final hand-in material in submission.

Before the first task

Record your operating system and the installed application versions. Confirm that the file extensions are visible and that you can create a CSV, open a PDF and make a ZIP. Avoid syncing personal or confidential data into this case folder. The training pack is fictional; no purchase, live investigation account or collection from another person is needed.

PRACTICAL SETUP | WINDOWS, MACOS & LINUX

Installation & first-run checks

1 | Install a document and spreadsheet suite

Open the official LibreOffice download page and choose your operating system and CPU architecture. On Windows, download the stable main installer, run it and follow the standard setup prompts; open both Calc and Writer after installation. On macOS, choose Intel or Apple Silicon as appropriate, open the DMG and move LibreOffice to Applications. On Linux, prefer the distribution's supported software manager. Record the version in your case notes.

LibreOffice download and installation instructions

2 | Set up a plain-text editor

Download VS Code from its official site if you do not already have a suitable editor. On Windows, the user installer normally avoids a machine-wide installation. Open only your working case folder using File > Open Folder. Inspect JSON or SQL as text, keep automatic file formatting off for evidence copies, and do not add extensions that are not needed. A built-in text editor is sufficient when installing VS Code is not possible.

Official VS Code Windows setup

3 | Verify hashes without an extra package

On Windows, open PowerShell in your working case folder and run Get-FileHash -Algorithm SHA256 .\originals\<filename>. On macOS use shasum -a 256 originals/<filename>. On Linux use sha256sum originals/<filename>. Replace the placeholder with one actual filename. Save each digest with its filename, size, date and tool. Repeating the command against the same preserved file should produce the same digest.

4 | Domain-specific installation and first run

Python 3 is optional for repeatable checks. Use the official Python download page, select a supported stable Python 3 distribution and follow its operating-system instructions. Open a new terminal and verify python --version, python3 --version or py --version as appropriate. Standard csv, json, hashlib, datetime and sqlite3 modules are enough for these labs; third-party packages are not required.

Python official downloads

Installation checks: create a test worksheet, export one PDF, read one source file from a working copy and reproduce a SHA-256 digest. Save a short tools.txt with versions and any differences from these instructions. Official setup pages are the source of truth if a vendor changes a screen label.

DOMAIN-SPECIFIC GUIDANCE

Worked method & reading library

First reproducible examination

Open file_inventory.csv as text columns, then activity.csv in a separate worksheet. Count source rows, create an exact-key lookup on file_record, and retain unmatched rows. Export your joined worksheet as analysis.csv without overwriting either source. Select a single row and explain the full path from source row to conclusion.

A limit you must state

A modified timestamp is not automatically the time of a deliberate human edit. This pack cannot establish deletion, original disk state, malware presence or the contents of a missing report.

Three books & substantial reference downloads

Use the original publisher or author links below. Reference guides and manuals are labelled separately from textbooks. Older editions provide background; they are not a substitute for current tool documentation. Third-party authors retain their rights and do not endorse PFSA.

1 | Guide to Integrating Forensic Techniques into Incident Response

Karen Kent et al. / NIST | SP 800-86, 2006 | Forensic reference guide

Read for evidence collection, examination, analysis and reporting concepts.

Open authorised PDF / author download page

2 | Incident Response Recommendations and Considerations for Cybersecurity Risk Management

Alexander Nelson et al. / NIST | SP 800-61 Rev. 3, 2025 | Incident response reference guide

Connect findings and evidence handling to a wider incident response process.

Open authorised PDF / author download page

3 | Guide to Malware Incident Prevention and Handling for Desktops and Laptops

Murugiah Souppaya and Karen Scarfone / NIST | SP 800-83 Rev. 1, 2013 | Defensive reference guide

Understand defensive handling and evidence context; the PFSA lab contains no live malware.

Open authorised PDF / author download page

Download links checked 13 November 2026. Use the source page if a PDF host changes or restricts automated downloads. These reading files are not required attachments to your weekly submission.

FINAL PAGE | PLAN, PRACTISE, VERIFY

Four-week learning roadmap

Your four-stage learning path

Evidence registration -> metadata comparison -> activity correlation -> supported case report

Use this roadmap to plan the sequence, not to calculate calendar deadlines. Staff publish the actual dates in your portal. Early Start changes when access opens; it does not remove any weekly deliverable or assessment requirement.

Stage	Suggested focus	Checkpoint before moving on
Week 1 | Preserve	Days 1-2: scope and inventory. Days 3-4: integrity and working copy. Days 5-7: review and submission.	Every source has an ID, hash and documented limitation.
Week 2 | Examine	Days 8-9: field definitions. Days 10-11: structured checks. Days 12-14: independent recheck and submission.	Derived tables retain original IDs and reproducible calculations.
Week 3 | Correlate	Days 15-16: time conversion. Days 17-18: source correlation. Days 19-21: alternatives and submission.	Timeline retains raw time and explains ambiguity, not just a neat order.
Week 4 | Communicate	Days 22-23: findings. Days 24-25: report and appendices. Days 26-28: independent review and final hand-in.	A reviewer can repeat the method and trace every significant claim.

Daily working habit

Start by reading your last case note and checking the source hash. Work on one defined question, save the method and result, then write a brief end-of-session note: completed work, decisions, outstanding questions and next step. Keep the final report consistent with the latest version of the analysis tables.

Final readiness gate

Confirm four genuine weekly submissions, complete evidence references, original-file integrity checks and an organised final report. Read staff feedback and resolve requested corrections. Keep a personal copy of the submitted package and the portal acknowledgement. Document eligibility and recommendation remain subject to assessment and the academy's published service terms.

What you should be able to demonstrate

Explain the supplied evidence boundary, reproduce one key finding, compare a competing explanation and describe which additional evidence would improve confidence. That explanation is more valuable than a screenshot of a tool running.

Student portal and Support
